Outline: Week 14

- Introduction to the Concept of Database Indexing
- Various Types of Database Indices
- Tradeoffs between Various Types of Database Indices

File-Based Approach

Database Management System (DBMS)

Database Management System (DBMS)

What should be the DBMS Interface?

What should be the DBMS Interface?

- Data Model
 - A collection of conceptual tools for describing data, data relationships, data semantics, and consistency constraints.

" " The Relational Model (TABLE-based Data Model)

- The relational model uses a collection of tables to represent both data and the relationships among those data.
- Its conceptual simplicity has led to its widespread adoption; a vast majority of database products are based on the relational model.

Sequential file for *instructor* records

Database Indexing: Motivation

- Consider the following query:
 - Find all instructors in the Physics department
- It is inefficient for the system to read every tuple in the *instructor* relation to check if *dept_name* value is Physics
 - Let's consider an alternative, inspired by the idea of index typically at the end of a book.

Sequential file for *instructor* records

Database Indexing: More about Analogy with Textbook Index

- Note the following about a textbook's index:
 - The words in the index are in sorted order, making it easy to find the word we want.
 - The index is much smaller than the textbook, further reducing the search effort needed.

10101	Srinivasan	Comp. Sci.	65000	
12121	Wu	Finance	90000	
15151	Mozart	Music	40000	
22222	Einstein	Physics	95000

98345	Kim	Elec. Eng.	80000	

Sequential file for *instructor* records

Database Indexing

- An index for a file in a database system works in much the same way as the index in a textbook.
 - For example, to retrieve a student record given an ID, the database system would look up an index to find on which disk block the corresponding record resides.
 - The disk block is then fetched, to get the appropriate student record.
- Search Key
 - The attribute (or set of attributes) whose values are used to look up records in a table/file

- Index File

- An index file consists of records (index entries) of the form:

search-key value

pointer to the record on disk

The pointer consists of an identifier of a disk block and an offset within the disk block to identify the record.

- Index files are typically much smaller than the original database files.

Multiple Indices on a Database File

- A database file may have several indices on different search keys.

Not All Indices are Created Equal!!

- Consider implementing an index on a very large student relation by keeping a sorted list of student IDs
 - It would not work very well because:
 - i) the index would itself be very big
 - ii) even though keeping the index sorted reduces the search time, finding the student can still be rather time-consuming
 - iii) updating a sorted list as students are added or removed from the database can be quite expensive

Figure 4.1 The *student* relation.

Index Evaluation Metrics

- We shall consider several techniques of indexing.
 - No one technique is best.
 - Each technique is best suited to particular database applications.
 - These techniques can be evaluated based on the following factors:
- 1) • Access types: The types of access that are supported efficiently. Access types can include finding records with a specified attribute value and finding records whose attribute values fall in a specified range.
 - 2) • Access time: The time it takes to find a particular data item, or set of items, using the technique in question.
 - 3) • Insertion time: The time it takes to insert a new data item. This value includes the time it takes to find the correct place to insert the new data item, as well as the time it takes to update the index structure.
 - 4) • Deletion time: The time it takes to delete a data item. This value includes the time it takes to find the item to be deleted, as well as the time it takes to update the index structure.
 - 5) • Space overhead: The additional space occupied by an index structure. Provided that the amount of additional space is moderate, it is usually worthwhile to sacrifice the space to achieve improved performance.

$$j = h(x)$$

$$1 = h(\text{PHYSICS})$$

$$2 = h(\text{BIO})$$

$$3 = h(\text{MUSIC}) \quad h(\text{EE}) = 3$$

Types of Indices

• Ordered indices

- Based on a sorted ordering of the key values.

• Hash indices

- Based on a uniform distribution of key values across a range of buckets. The bucket to which a value is assigned is determined by a function, called a *hash function*.

HASH INDEX

ORDERED INDEX

Sequential file for *instructor* records

Ordered Index

- An ordered index stores the values of the search keys in sorted order and associates with each search-key value the records that contain that value.
- The records in the indexed file may themselves be stored in some sorted order (not necessarily the order of the search key in the index structure).

Types of Ordered Indices: Clustering vs Non-Clustering

- **Clustering Index (Clustered Index)**

- If the database file containing the records/tuples is sequentially ordered, a clustering index is an index whose search key also defines the sequential order of the file.
- Also known as Primary Index.

- **Non-Clustering Index (Non-Clustered Index)**

- A non-clustering index is an index whose search key does not define the sequential order of the database file.
- Also known as Secondary Index.

Exmpl- Find ID= 22222

Types of Ordered Indices: Dense vs Sparse

- **Dense Index**

- In a dense index, an index entry appears in the index for every search-key value in the database file.

- **Sparse Index**

- In a sparse index, an index entry appears in the index for only some of the search-key value in the database file.

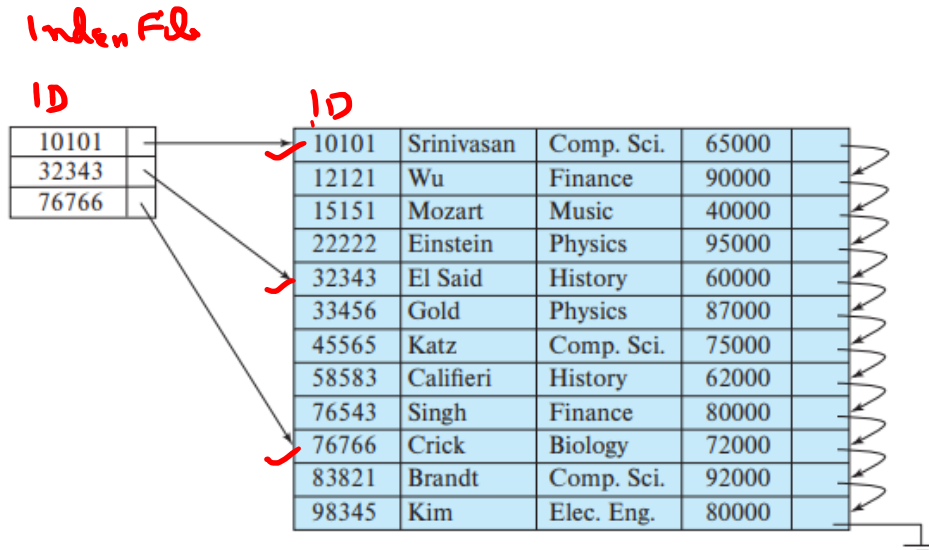

Figure 14.3 Sparse index.

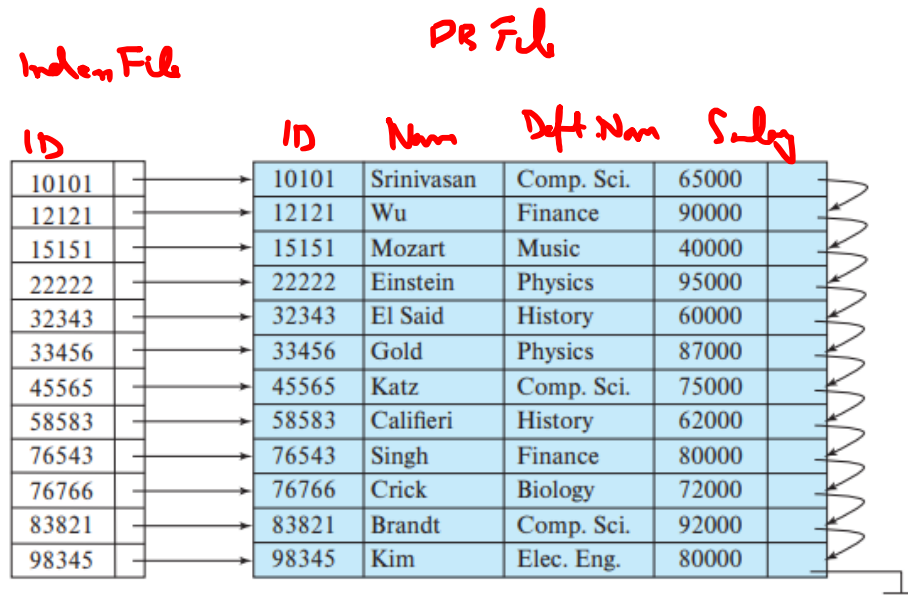

Figure 14.2 Dense index.

1) Dense / Sparse?

2) Clustering / non clustering

Dense Clustering Index vs Dense Non-Clustering Index

- Dense Clustering Index**

- In a dense clustering index, the index record contains the search-key value and a pointer to the first data record with that search-key value. The rest of the data records with the same search-key value would be stored sequentially after the first record.

- Dense Non-Clustering Index**

- In a dense non-clustering index, the index must store a list of pointers to all records with the same search-key value.

Dense Clustering Index vs Dense Non-Clustering Index

- Dense Clustering Index**

- In a dense clustering index, the index record contains the search-key value and a pointer to the first data record with that search-key value. The rest of the data records with the same search-key value would be stored sequentially after the first record.

- Dense Non-Clustering Index**

- In a dense non-clustering index, the index must store a list of pointers to all records with the same search-key value.
 - As an alternative, an index record can point to a bucket that contains pointers to all the actual records with that particular search-key value.

Sparse Clustering Index

- For a sparse clustering index
 - Each index entry contains a search-key value and a pointer to the first data record with that search-key value. To locate a record, we find the index entry with the largest search-key value that is less than or equal to the search-key value for which we are looking. We start at the record pointed to by that index entry and follow the pointers in the file until we find the desired record.

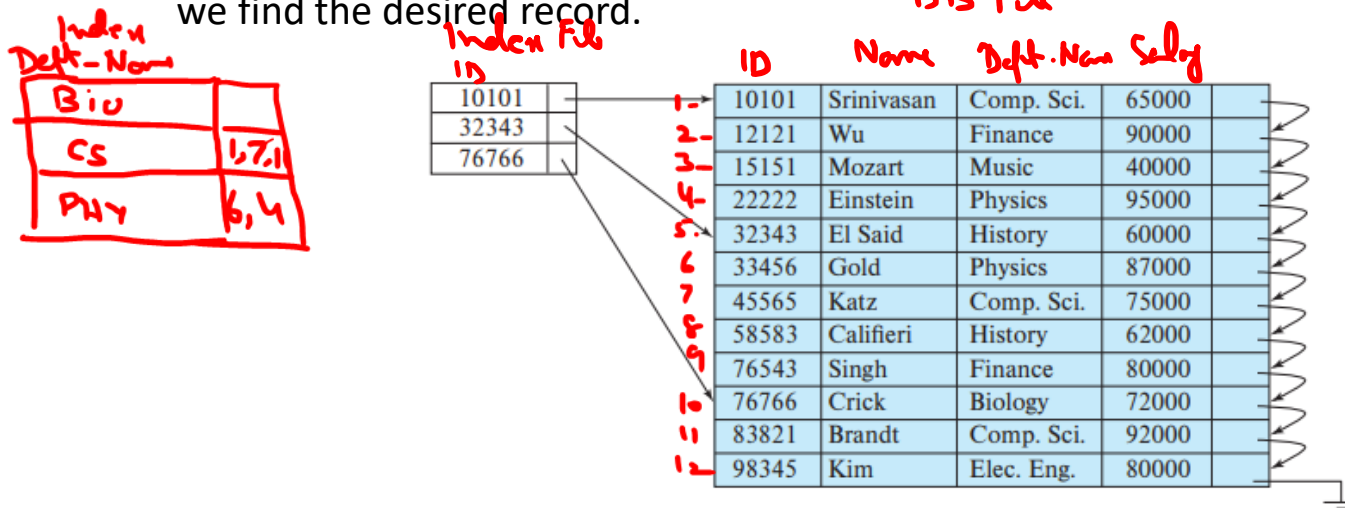

Figure 14.3 Sparse index.

- Sparse Non-Clustering Index?

Dense vs Sparse Indices: Tradeoff between Access Time and Space Overhead

- It is generally faster to locate a record if we have a dense index, rather than a sparse index.
- However, sparse indices have advantages over dense indices in that they require less space and they impose less maintenance overhead for insertions and deletions.

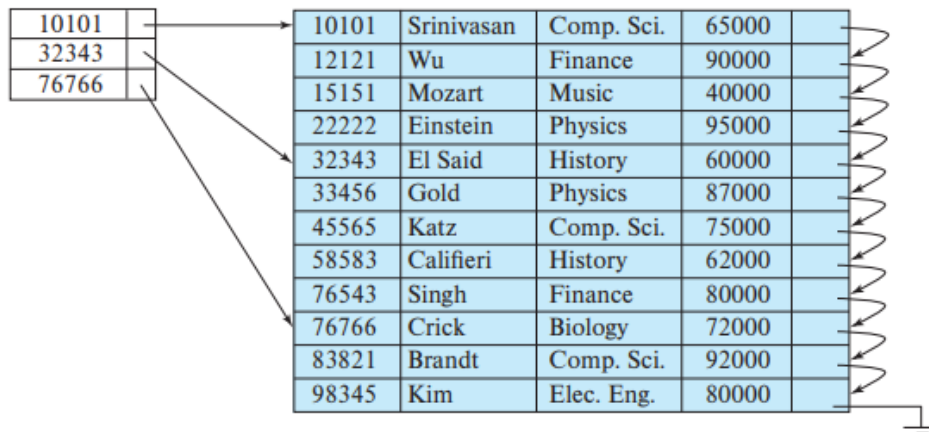

Figure 14.3 Sparse index.

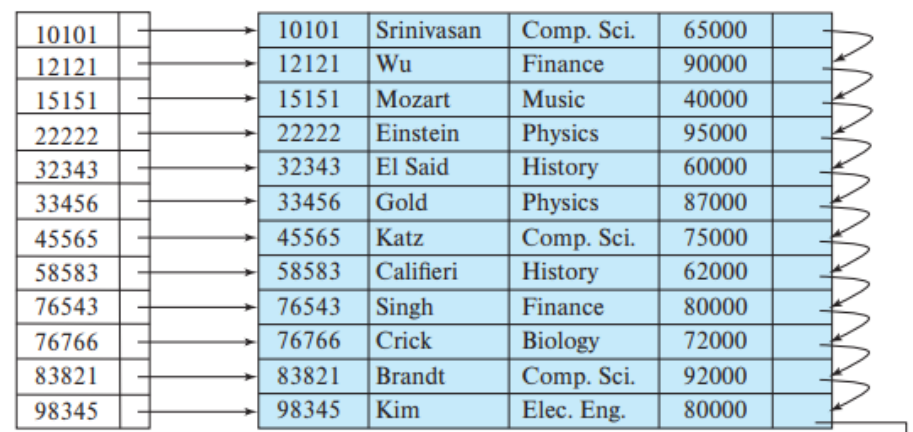

Figure 14.2 Dense index.

Dense vs Sparse Indices: Tradeoff between Access Time and Space Overhead

- A good compromise
 - A sparse index with one index entry per disk block
 - Reason: The dominant cost in processing a database request is the time that it takes to bring a block from disk into main memory. Once we have brought in the block, the time to scan the entire block is negligible.

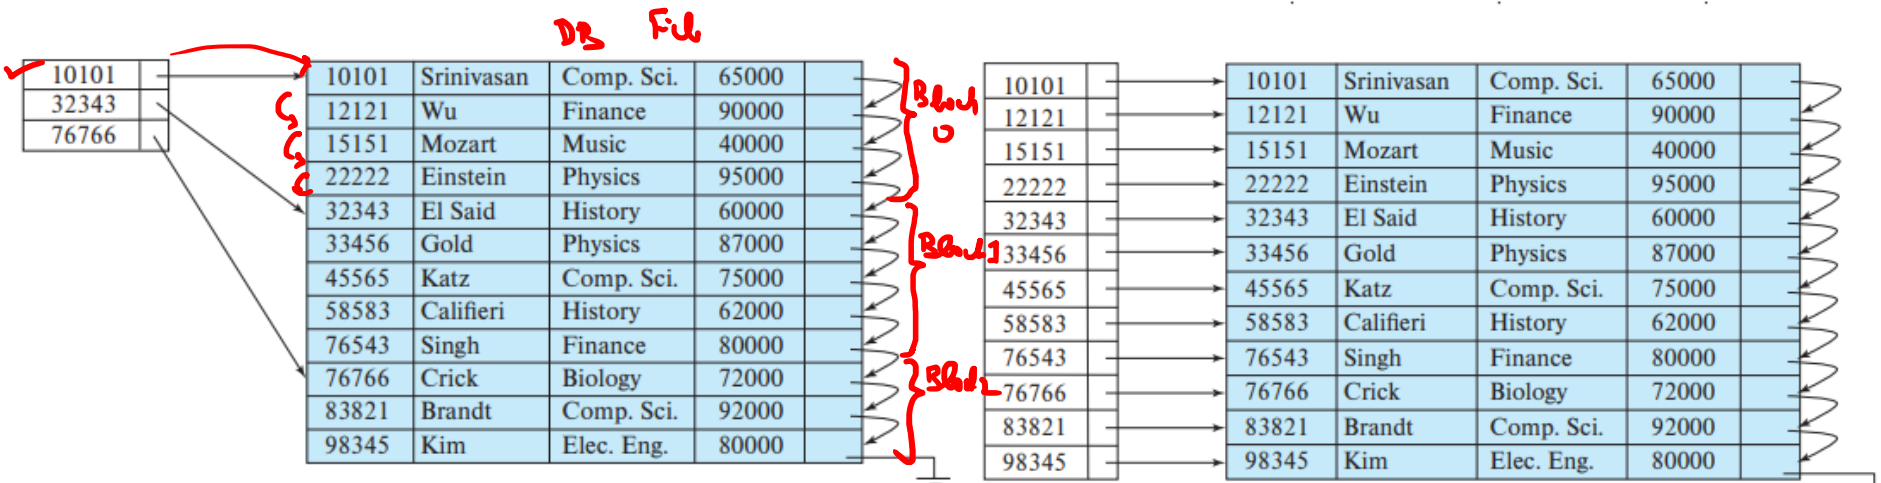

Figure 14.3 Sparse index.

Figure 14.2 Dense index.

Multi-Level Indices: Motivation

- If an index is small enough to be kept entirely in main memory, the search time to find an entry is low.
- However, if the index is so large that not all of it can be kept in memory, index blocks must be fetched from disk when required.

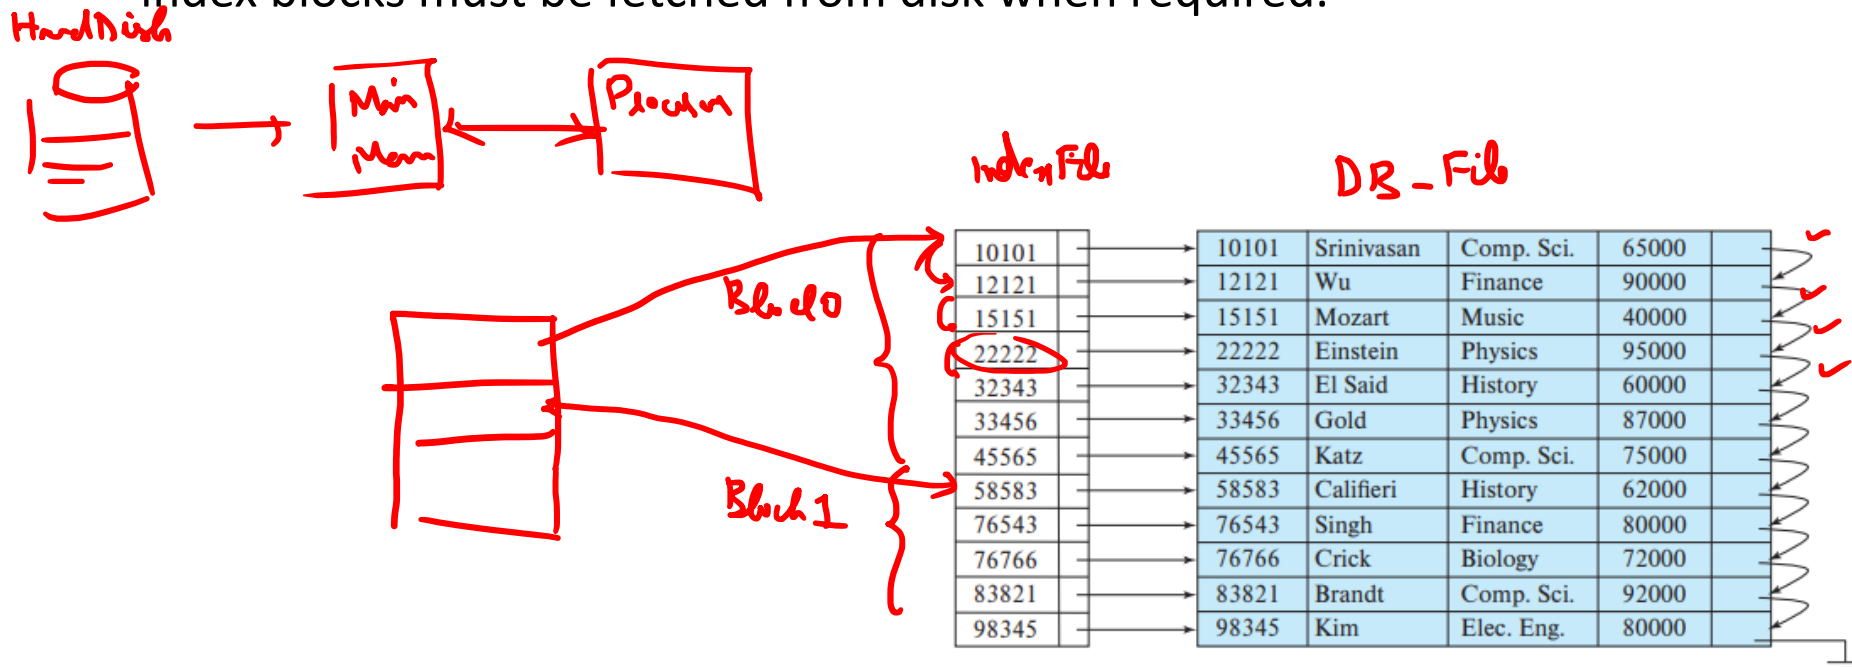

Figure 14.2 Dense index.

Multi-Level Indices

- If index does not fit in memory, access becomes expensive.
 - Solution: treat index kept on disk as a sequential file and construct a sparse index on it.
- Outer index
 - a sparse index of the basic index
- inner index
 - the basic index file
- If even outer index is too large to fit in main memory, yet another level of index can be created, and so on.

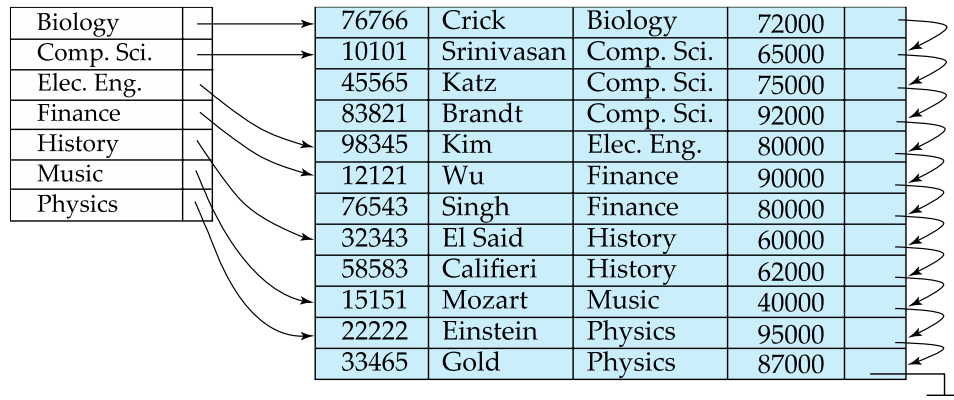

Figure 14.5 Two-level sparse index.
